Array methods

Arrays provide a lot of methods. To make things easier, in this chapter they are split into groups.

Add/remove items

We already know methods that add and remove items from the beginning or the end:

- `arr.push(...items)` – adds items to the end,
- `arr.pop()` – extracts an item from the end,
- `arr.shift()` – extracts an item from the beginning,
- `arr.unshift(...items)` – adds items to the beginning.

Here are a few others.

splice

How to delete an element from the array?

The arrays are objects, so we can try to use `delete`:

```
1  let arr = ["I", "go", "home"];
2
3  delete arr[1]; // remove "go"
4
5  alert( arr[1] ); // undefined
6
7  // now arr = ["I",  , "home"];
8  alert( arr.length ); // 3
```

The element was removed, but the array still has 3 elements, we can see that `arr.length == 3`.

That's natural, because `delete obj.key` removes a value by the `key`. It's all it does. Fine for objects. But for arrays we usually want the rest of elements to shift and occupy the freed place. We expect to have a shorter array now.

So, special methods should be used.

The arr.splice(start) method is a swiss army knife for arrays. It can do everything: insert, remove and replace elements.

The syntax is:

```
1  arr.splice(index[, deleteCount, elem1, ..., elemN])
```

It starts from the position `index`: removes `deleteCount` elements and then inserts `elem1, ..., elemN` at their place. Returns the array of removed elements.

This method is easy to grasp by examples.

Let's start with the deletion:

```
1  let arr = ["I", "study", "JavaScript"];
2
3  arr.splice(1, 1); // from index 1 remove 1 element
4
5  alert( arr ); // ["I", "JavaScript"]
```

Easy, right? Starting from the index `1` it removed `1` element.

In the next example we remove 3 elements and replace them with the other two:

```
1  let arr = ["I", "study", "JavaScript", "right", "now"];
2
3  // remove 3 first elements and replace them with another
4  arr.splice(0, 3, "Let's", "dance");
5
6  alert( arr ) // now ["Let's", "dance", "right", "now"]
```

Here we can see that `splice` returns the array of removed elements:

```
1  let arr = ["I", "study", "JavaScript", "right", "now"];
2
3  // remove 2 first elements
4  let removed = arr.splice(0, 2);
5
6  alert( removed ); // "I", "study" <-- array of removed elements
```

The `splice` method is also able to insert the elements without any removals. For that we need to set `deleteCount` to `0`:

```
1  let arr = ["I", "study", "JavaScript"];
2
3  // from index 2
4  // delete 0
5  // then insert "complex" and "language"
6  arr.splice(2, 0, "complex", "language");
7
8  alert( arr ); // "I", "study", "complex", "language", "JavaScript"
```

> ℹ️ **Negative indexes allowed**
>
> Here and in other array methods, negative indexes are allowed. They specify the position from the end of the array, like here:
>
> ```
> 1  let arr = [1, 2, 5];
> 2
> 3  // from index -1 (one step from the end)
> 4  // delete 0 elements,
> 5  // then insert 3 and 4
> 6  arr.splice(-1, 0, 3, 4);
> 7
> 8  alert( arr ); // 1,2,3,4,5
> ```

slice

The method [arr.slice](#) is much simpler than similar-looking `arr.splice`.

The syntax is:

```
1  arr.slice([start], [end])
```

It returns a new array copying to it all items from index `start` to `end` (not including `end`). Both `start` and `end` can be negative, in that case position from array end is assumed.

It's similar to a string method `str.slice`, but instead of substrings it makes subarrays.

For instance:

```
1  let arr = ["t", "e", "s", "t"];
2
3  alert( arr.slice(1, 3) ); // e,s (copy from 1 to 3)
4
5  alert( arr.slice(-2) ); // s,t (copy from -2 till the end)
```

We can also call it without arguments: `arr.slice()` creates a copy of `arr`. That's often used to obtain a copy for further transformations that should not affect the original array.

concat

The method [arr.concat](#) creates a new array that includes values from other arrays and additional items.

The syntax is:

```
1  arr.concat(arg1, arg2...)
```

It accepts any number of arguments – either arrays or values.

The result is a new array containing items from `arr`, then `arg1`, `arg2` etc.

If an argument `argN` is an array, then all its elements are copied. Otherwise, the argument itself is copied.

For instance:

```
 1  let arr = [1, 2];
 2
 3  // create an array from: arr and [3,4]
 4  alert( arr.concat([3, 4]) ); // 1,2,3,4
 5
 6  // create an array from: arr and [3,4] and [5,6]
 7  alert( arr.concat([3, 4], [5, 6]) ); // 1,2,3,4,5,6
 8
 9  // create an array from: arr and [3,4], then add values 5 and 6
10  alert( arr.concat([3, 4], 5, 6) ); // 1,2,3,4,5,6
```

Normally, it only copies elements from arrays. Other objects, even if they look like arrays, are added as a whole:

```
 1  let arr = [1, 2];
 2
 3  let arrayLike = {
 4    0: "something",
 5    length: 1
 6  };
 7
 8  alert( arr.concat(arrayLike) ); // 1,2,[object Object]
```

…But if an array-like object has a special `Symbol.isConcatSpreadable` property, then it's treated as an array by `concat`: its elements are added instead:

```
 1  let arr = [1, 2];
 2
 3  let arrayLike = {
 4    0: "something",
 5    1: "else",
 6    [Symbol.isConcatSpreadable]: true,
 7    length: 2
 8  };
 9
10  alert( arr.concat(arrayLike) ); // 1,2,something,else
```

Iterate: forEach

The arr.forEach method allows to run a function for every element of the array.

The syntax:

```
1  arr.forEach(function(item, index, array) {
2    // ... do something with item
3  });
```

For instance, this shows each element of the array:

```
1  // for each element call alert
2  ["Bilbo", "Gandalf", "Nazgul"].forEach(alert);
```

And this code is more elaborate about their positions in the target array:

```
1  ["Bilbo", "Gandalf", "Nazgul"].forEach((item, index, array) => {
2    alert(`${item} is at index ${index} in ${array}`);
3  });
```

The result of the function (if it returns any) is thrown away and ignored.

Searching in array

Now let's cover methods that search in an array.

indexOf/lastIndexOf and includes

The methods arr.indexOf, arr.lastIndexOf and arr.includes have the same syntax and do essentially the same as their string counterparts, but operate on items instead of characters:

- `arr.indexOf(item, from)` — looks for `item` starting from index `from`, and returns the index where it was found, otherwise `-1`.
- `arr.lastIndexOf(item, from)` — same, but looks for from right to left.
- `arr.includes(item, from)` — looks for `item` starting from index `from`, returns `true` if found.

For instance:

```
1 let arr = [1, 0, false];
2
3 alert( arr.indexOf(0) ); // 1
4 alert( arr.indexOf(false) ); // 2
5 alert( arr.indexOf(null) ); // -1
6
7 alert( arr.includes(1) ); // true
```

Note that the methods use `===` comparison. So, if we look for `false`, it finds exactly `false` and not the zero.

If we want to check for inclusion, and don't want to know the exact index, then `arr.includes` is preferred.

Also, a very minor difference of `includes` is that it correctly handles `NaN`, unlike `indexOf/lastIndexOf`:

```
1 const arr = [NaN];
2 alert( arr.indexOf(NaN) ); // -1 (should be 0, but === equality doesn't work for NaN)
3 alert( arr.includes(NaN) );// true (correct)
```

find and findIndex

Imagine we have an array of objects. How do we find an object with the specific condition?

Here the arr.find(fn) method comes in handy.

The syntax is:

```
1 let result = arr.find(function(item, index, array) {
2   // if true is returned, item is returned and iteration is stopped
3   // for falsy scenario returns undefined
4 });
```

The function is called for elements of the array, one after another:

- `item` is the element.
- `index` is its index.
- `array` is the array itself.

If it returns `true`, the search is stopped, the `item` is returned. If nothing found, `undefined` is returned.

For example, we have an array of users, each with the fields `id` and `name`. Let's find the one with `id == 1`:

```
1 let users = [
2   {id: 1, name: "John"},
3   {id: 2, name: "Pete"},
4   {id: 3, name: "Mary"}
5 ];
6
7 let user = users.find(item => item.id == 1);
8
9 alert(user.name); // John
```

In real life arrays of objects is a common thing, so the `find` method is very useful.

Note that in the example we provide to `find` the function `item => item.id == 1` with one argument. That's typical, other arguments of this function are rarely used.

The arr.findIndex method is essentially the same, but it returns the index where the element was found instead of the element itself and `-1` is returned when nothing is found.

filter

The `find` method looks for a single (first) element that makes the function return `true`.

If there may be many, we can use arr.filter(fn).

The syntax is similar to `find`, but `filter` returns an array of all matching elements:

```
1 let results = arr.filter(function(item, index, array) {
2   // if true item is pushed to results and the iteration continues
3   // returns empty array if nothing found
4 });
```

For instance:

```
1  let users = [
2    {id: 1, name: "John"},
3    {id: 2, name: "Pete"},
4    {id: 3, name: "Mary"}
5  ];
6
7  // returns array of the first two users
8  let someUsers = users.filter(item => item.id < 3);
9
10 alert(someUsers.length); // 2
```

Transform an array

Let's move on to methods that transform and reorder an array.

map

The arr.map method is one of the most useful and often used.

It calls the function for each element of the array and returns the array of results.

The syntax is:

```
1  let result = arr.map(function(item, index, array) {
2    // returns the new value instead of item
3  });
```

For instance, here we transform each element into its length:

```
1  let lengths = ["Bilbo", "Gandalf", "Nazgul"].map(item => item.length);
2  alert(lengths); // 5,7,6
```

sort(fn)

The call to arr.sort() sorts the array *in place*, changing its element order.

It also returns the sorted array, but the returned value is usually ignored, as `arr` itself is modified.

For instance:

```
1  let arr = [ 1, 2, 15 ];
2
3  // the method reorders the content of arr
4  arr.sort();
5
6  alert( arr );   // 1, 15, 2
```

Did you notice anything strange in the outcome?

The order became `1, 15, 2`. Incorrect. But why?

The items are sorted as strings by default.

Literally, all elements are converted to strings for comparisons. For strings, lexicographic ordering is applied and indeed `"2" > "15"`.

To use our own sorting order, we need to supply a function as the argument of `arr.sort()`.

The function should compare two arbitrary values and return:

```
1  function compare(a, b) {
2    if (a > b) return 1; // if the first value is greater than the second
3    if (a == b) return 0; // if values are equal
4    if (a < b) return -1; // if the first value is less than the second
5  }
```

For instance, to sort as numbers:

```
1  function compareNumeric(a, b) {
2    if (a > b) return 1;
3    if (a == b) return 0;
4    if (a < b) return -1;
5  }
6
7  let arr = [ 1, 2, 15 ];
8
9  arr.sort(compareNumeric);
```

```
10
11  alert(arr);  // 1, 2, 15
```

Now it works as intended.

Let's step aside and think what's happening. The `arr` can be array of anything, right? It may contain numbers or strings or objects or whatever. We have a set of *some items*. To sort it, we need an *ordering function* that knows how to compare its elements. The default is a string order.

The `arr.sort(fn)` method implements a generic sorting algorithm. We don't need to care how it internally works (an optimized quicksort most of the time). It will walk the array, compare its elements using the provided function and reorder them, all we need is to provide the `fn` which does the comparison.

By the way, if we ever want to know which elements are compared – nothing prevents from alerting them:

```
1  [1, -2, 15, 2, 0, 8].sort(function(a, b) {
2    alert( a + " <> " + b );
3  });
```

The algorithm may compare an element with multiple others in the process, but it tries to make as few comparisons as possible.

> ℹ️ **A comparison function may return any number**
>
> Actually, a comparison function is only required to return a positive number to say "greater" and a negative number to say "less".
>
> That allows to write shorter functions:
>
> ```
> 1  let arr = [ 1, 2, 15 ];
> 2
> 3  arr.sort(function(a, b) { return a - b; });
> 4
> 5  alert(arr);  // 1, 2, 15
> ```

> ℹ️ **Arrow functions for the best**
>
> Remember arrow functions? We can use them here for neater sorting:
>
> ```
> 1  arr.sort( (a, b) => a - b );
> ```
>
> This works exactly the same as the longer version above.

reverse

The method arr.reverse reverses the order of elements in `arr`.

For instance:

```
1  let arr = [1, 2, 3, 4, 5];
2  arr.reverse();
3
4  alert( arr ); // 5,4,3,2,1
```

It also returns the array `arr` after the reversal.

split and join

Here's the situation from real life. We are writing a messaging app, and the person enters the comma-delimited list of receivers: `John, Pete, Mary`. But for us an array of names would be much more comfortable than a single string. How to get it?

The str.split(delim) method does exactly that. It splits the string into an array by the given delimiter `delim`.

In the example below, we split by a comma followed by space:

```
1  let names = 'Bilbo, Gandalf, Nazgul';
2
3  let arr = names.split(', ');
4
5  for (let name of arr) {
6    alert( `A message to ${name}.` ); // A message to Bilbo  (and other names)
7  }
```

The split method has an optional second numeric argument – a limit on the array length. If it is provided, then the extra elements are ignored. In practice it is rarely used though:

```
1  let arr = 'Bilbo, Gandalf, Nazgul, Saruman'.split(', ', 2);
2
3  alert(arr); // Bilbo, Gandalf
```

> ℹ️ **Split into letters**
>
> The call to split(s) with an empty s would split the string into an array of letters:
>
> ```
> 1  let str = "test";
> 2
> 3  alert( str.split('') ); // t,e,s,t
> ```

The call arr.join(glue) does the reverse to split . It creates a string of arr items joined by glue between them.

For instance:

```
1  let arr = ['Bilbo', 'Gandalf', 'Nazgul'];
2
3  let str = arr.join(';'); // glue the array into a string using ;
4
5  alert( str ); // Bilbo;Gandalf;Nazgul
```

reduce/reduceRight

When we need to iterate over an array – we can use forEach , for or for..of .

When we need to iterate and return the data for each element – we can use map .

The methods arr.reduce and arr.reduceRight also belong to that breed, but are a little bit more intricate. They are used to calculate a single value based on the array.

The syntax is:

```
1  let value = arr.reduce(function(previousValue, item, index, array) {
2    // ...
3  }, [initial]);
```

The function is applied to all array elements one after another and "carries on" its result to the next call.

Arguments:

- previousValue – is the result of the previous function call, equals initial the first time (if initial is provided).
- item – is the current array item.
- index – is its position.
- array – is the array.

As function is applied, the result of the previous function call is passed to the next one as the first argument.

Sounds complicated, but it's not if you think about the first argument as the "accumulator" that stores the combined result of all previous execution. And at the end it becomes the result of reduce .

The easiest way to grasp that is by example.

Here we get a sum of an array in one line:

```
1  let arr = [1, 2, 3, 4, 5];
2
3  let result = arr.reduce((sum, current) => sum + current, 0);
4
5  alert(result); // 15
```

The function passed to reduce uses only 2 arguments, that's typically enough.

Let's see the details of what's going on.

1. On the first run, sum is the initial value (the last argument of reduce), equals 0 , and current is the first array element, equals 1 . So the function result is 1 .
2. On the second run, sum = 1 , we add the second array element (2) to it and return.
3. On the 3rd run, sum = 3 and we add one more element to it, and so on…

The calculation flow:

```
sum        sum        sum        sum        sum
0          0+1        0+1+2      0+1+2+3    0+1+2+3+4
current    current    current    current    current
1          2          3          4          5
```

| 1 | 2 | 3 | 4 | 5 |

⟶ 0+1+2+3+4+5 = 15

Or in the form of a table, where each row represents a function call on the next array element:

	sum	current	result
the first call	0	1	1
the second call	1	2	3
the third call	3	3	6
the fourth call	6	4	10
the fifth call	10	5	15

Here we can clearly see how the result of the previous call becomes the first argument of the next one.

We also can omit the initial value:

```
1  let arr = [1, 2, 3, 4, 5];
2
3  // removed initial value from reduce (no 0)
4  let result = arr.reduce((sum, current) => sum + current);
5
6  alert( result ); // 15
```

The result is the same. That's because if there's no initial, then `reduce` takes the first element of the array as the initial value and starts the iteration from the 2nd element.

The calculation table is the same as above, minus the first row.

But such use requires an extreme care. If the array is empty, then `reduce` call without initial value gives an error.

Here's an example:

```
1  let arr = [];
2
3  // Error: Reduce of empty array with no initial value
4  // if the initial value existed, reduce would return it for the empty arr.
5  arr.reduce((sum, current) => sum + current);
```

So it's advised to always specify the initial value.

The method arr.reduceRight does the same, but goes from right to left.

Array.isArray

Arrays do not form a separate language type. They are based on objects.

So `typeof` does not help to distinguish a plain object from an array:

```
1  alert(typeof {}); // object
2  alert(typeof []); // same
```

…But arrays are used so often that there's a special method for that: Array.isArray(value). It returns `true` if the `value` is an array, and `false` otherwise.

```
1  alert(Array.isArray({})); // false
2
3  alert(Array.isArray([])); // true
```

Most methods support "thisArg"

Almost all array methods that call functions – like `find`, `filter`, `map`, with a notable exception of `sort`, accept an optional additional parameter `thisArg`.

That parameter is not explained in the sections above, because it's rarely used. But for completeness we have to cover it.

Here's the full syntax of these methods:

```
1  arr.find(func, thisArg);
2  arr.filter(func, thisArg);
```

```
3  arr.map(func, thisArg);
4  // ...
5  // thisArg is the optional last argument
```

The value of `thisArg` parameter becomes `this` for `func`.

For example, here we use a method of `army` object as a filter, and `thisArg` passes the context:

```
1  let army = {
2    minAge: 18,
3    maxAge: 27,
4    canJoin(user) {
5      return user.age >= this.minAge && user.age < this.maxAge;
6    }
7  };
8
9  let users = [
10    {age: 16},
11    {age: 20},
12    {age: 23},
13    {age: 30}
14  ];
15
16  // find users, for who army.canJoin returns true
17  let soldiers = users.filter(army.canJoin, army);
18
19  alert(soldiers.length); // 2
20  alert(soldiers[0].age); // 20
21  alert(soldiers[1].age); // 23
```

If in the example above we used `users.filter(army.canJoin)`, then `army.canJoin` would be called as a standalone function, with `this=undefined`, thus leading to an instant error.

A call to `users.filter(army.canJoin, army)` can be replaced with `users.filter(user => army.canJoin(user))`, that does the same. The former is used more often, as it's a bit easier to understand for most people.

Summary

A cheat sheet of array methods:

- To add/remove elements:

  - `push(...items)` – adds items to the end,
  - `pop()` – extracts an item from the end,
  - `shift()` – extracts an item from the beginning,
  - `unshift(...items)` – adds items to the beginning.
  - `splice(pos, deleteCount, ...items)` – at index `pos` delete `deleteCount` elements and insert `items`.
  - `slice(start, end)` – creates a new array, copies elements from position `start` till `end` (not inclusive) into it.
  - `concat(...items)` – returns a new array: copies all members of the current one and adds `items` to it. If any of `items` is an array, then its elements are taken.
- To search among elements:

  - `indexOf/lastIndexOf(item, pos)` – look for `item` starting from position `pos`, return the index or `-1` if not found.
  - `includes(value)` – returns `true` if the array has `value`, otherwise `false`.
  - `find/filter(func)` – filter elements through the function, return first/all values that make it return `true`.
  - `findIndex` is like `find`, but returns the index instead of a value.
- To iterate over elements:

  - `forEach(func)` – calls `func` for every element, does not return anything.
- To transform the array:

  - `map(func)` – creates a new array from results of calling `func` for every element.
  - `sort(func)` – sorts the array in-place, then returns it.
  - `reverse()` – reverses the array in-place, then returns it.
  - `split/join` – convert a string to array and back.
  - `reduce(func, initial)` – calculate a single value over the array by calling `func` for each element and passing an intermediate result between the calls.
- Additionally:

  - `Array.isArray(arr)` checks `arr` for being an array.

Please note that methods `sort`, `reverse` and `splice` modify the array itself.

These methods are the most used ones, they cover 99% of use cases. But there are few others:

- arr.some(fn)/arr.every(fn) checks the array.

The function `fn` is called on each element of the array similar to `map`. If any/all results are `true`, returns `true`, otherwise `false`.

- arr.fill(value, start, end) – fills the array with repeating `value` from index `start` to `end`.

- arr.copyWithin(target, start, end) – copies its elements from position `start` till position `end` into *itself*, at position `target` (overwrites existing).

For the full list, see the manual.

From the first sight it may seem that there are so many methods, quite difficult to remember. But actually that's much easier.

Look through the cheat sheet just to be aware of them. Then solve the tasks of this chapter to practice, so that you have experience with array methods.

Afterwards whenever you need to do something with an array, and you don't know how – come here, look at the cheat sheet and find the right method. Examples will help you to write it correctly. Soon you'll automatically remember the methods, without specific efforts from your side.

✅ Tasks

Translate border-left-width to borderLeftWidth ↗

importance: 5

Write the function `camelize(str)` that changes dash-separated words like "my-short-string" into camel-cased "myShortString".

That is: removes all dashes, each word after dash becomes uppercased.

Examples:

```
1  camelize("background-color") == 'backgroundColor';
2  camelize("list-style-image") == 'listStyleImage';
3  camelize("-webkit-transition") == 'WebkitTransition';
```

P.S. Hint: use `split` to split the string into an array, transform it and `join` back.

Open a sandbox with tests.

(solution)

Filter range ↗

importance: 4

Write a function `filterRange(arr, a, b)` that gets an array `arr`, looks for elements between `a` and `b` in it and returns an array of them.

The function should not modify the array. It should return the new array.

For instance:

```
1  let arr = [5, 3, 8, 1];
2
3  let filtered = filterRange(arr, 1, 4);
4
5  alert( filtered ); // 3,1 (matching values)
6
7  alert( arr ); // 5,3,8,1 (not modified)
```

Open a sandbox with tests.

(solution)

Filter range "in place" ↗

importance: 4

Write a function `filterRangeInPlace(arr, a, b)` that gets an array `arr` and removes from it all values except those that are between `a` and `b`. The test is: `a ≤ arr[i] ≤ b`.

The function should only modify the array. It should not return anything.

For instance:

```
1  let arr = [5, 3, 8, 1];
2
3  filterRangeInPlace(arr, 1, 4); // removed the numbers except from 1 to 4
4
5  alert( arr ); // [3, 1]
```

(solution)

Sort in decreasing order ↗

importance: 4

```
1  let arr = [5, 2, 1, -10, 8];
2
3  // ... your code to sort it in decreasing order
4
5  alert( arr ); // 8, 5, 2, 1, -10
```

(solution)

Copy and sort array ↗

importance: 5

We have an array of strings `arr`. We'd like to have a sorted copy of it, but keep `arr` unmodified.

Create a function `copySorted(arr)` that returns such a copy.

```
1  let arr = ["HTML", "JavaScript", "CSS"];
2
3  let sorted = copySorted(arr);
4
5  alert( sorted ); // CSS, HTML, JavaScript
6  alert( arr ); // HTML, JavaScript, CSS (no changes)
```

(solution)

Create an extendable calculator ↗

importance: 5

Create a constructor function `Calculator` that creates "extendable" calculator objects.

The task consists of two parts.

1.

    First, implement the method `calculate(str)` that takes a string like `"1 + 2"` in the format "NUMBER operator NUMBER" (space-delimited) and returns the result. Should understand plus `+` and minus `-`.

    Usage example:

    ```
    1  let calc = new Calculator;
    2
    3  alert( calc.calculate("3 + 7") ); // 10
    ```

2.

    Then add the method `addMethod(name, func)` that teaches the calculator a new operation. It takes the operator `name` and the two-argument function `func(a,b)` that implements it.

    For instance, let's add the multiplication `*`, division `/` and power `**`:

    ```
    1  let powerCalc = new Calculator;
    2  powerCalc.addMethod("*", (a, b) => a * b);
    3  powerCalc.addMethod("/", (a, b) => a / b);
    4  powerCalc.addMethod("**", (a, b) => a ** b);
    5
    6  let result = powerCalc.calculate("2 ** 3");
    7  alert( result ); // 8
    ```

- No parentheses or complex expressions in this task.
- The numbers and the operator are delimited with exactly one space.
- There may be error handling if you'd like to add it.

(solution)

Map to names ↗

importance: 5

You have an array of `user` objects, each one has `user.name`. Write the code that converts it into an array of names.

For instance:

```
1  let john = { name: "John", age: 25 };
2  let pete = { name: "Pete", age: 30 };
3  let mary = { name: "Mary", age: 28 };
4
5  let users = [ john, pete, mary ];
6
7  let names = /* ... your code */
8
9  alert( names ); // John, Pete, Mary
```

(solution)

Map to objects ↗

importance: 5

You have an array of `user` objects, each one has `name`, `surname` and `id`.

Write the code to create another array from it, of objects with `id` and `fullName`, where `fullName` is generated from `name` and `surname`.

For instance:

```
1  let john = { name: "John", surname: "Smith", id: 1 };
2  let pete = { name: "Pete", surname: "Hunt", id: 2 };
3  let mary = { name: "Mary", surname: "Key", id: 3 };
4
5  let users = [ john, pete, mary ];
6
7  let usersMapped = /* ... your code ... */
8
9  /*
10 usersMapped = [
11   { fullName: "John Smith", id: 1 },
12   { fullName: "Pete Hunt", id: 2 },
13   { fullName: "Mary Key", id: 3 }
14 ]
15 */
16
17 alert( usersMapped[0].id ) // 1
18 alert( usersMapped[0].fullName ) // John Smith
```

So, actually you need to map one array of objects to another. Try using `=>` here. There's a small catch.

(solution)

Sort users by age ↗

importance: 5

Write the function `sortByAge(users)` that gets an array of objects with the `age` property and sorts them by `age`.

For instance:

```
1  let john = { name: "John", age: 25 };
2  let pete = { name: "Pete", age: 30 };
3  let mary = { name: "Mary", age: 28 };
4
```

```
 5  let arr = [ pete, john, mary ];
 6
 7  sortByAge(arr);
 8
 9  // now: [john, mary, pete]
10  alert(arr[0].name); // John
11  alert(arr[1].name); // Mary
12  alert(arr[2].name); // Pete
```

(solution)

Shuffle an array ↗

importance: 3

Write the function `shuffle(array)` that shuffles (randomly reorders) elements of the array.

Multiple runs of `shuffle` may lead to different orders of elements. For instance:

```
 1  let arr = [1, 2, 3];
 2
 3  shuffle(arr);
 4  // arr = [3, 2, 1]
 5
 6  shuffle(arr);
 7  // arr = [2, 1, 3]
 8
 9  shuffle(arr);
10  // arr = [3, 1, 2]
11  // ...
```

All element orders should have an equal probability. For instance, `[1,2,3]` can be reordered as `[1,2,3]` or `[1,3,2]` or `[3,1,2]` etc, with equal probability of each case.

(solution)

Get average age ↗

importance: 4

Write the function `getAverageAge(users)` that gets an array of objects with property `age` and returns the average age.

The formula for the average is `(age1 + age2 + ... + ageN) / N`.

For instance:

```
 1  let john = { name: "John", age: 25 };
 2  let pete = { name: "Pete", age: 30 };
 3  let mary = { name: "Mary", age: 29 };
 4
 5  let arr = [ john, pete, mary ];
 6
 7  alert( getAverageAge(arr) ); // (25 + 30 + 29) / 3 = 28
```

(solution)

Filter unique array members ↗

importance: 4

Let `arr` be an array.

Create a function `unique(arr)` that should return an array with unique items of `arr`.
For instance:

```
 1  function unique(arr) {
 2    /* your code */
 3  }
 4
 5  let strings = ["Hare", "Krishna", "Hare", "Krishna",
 6    "Krishna", "Krishna", "Hare", "Hare", ":-O"
 7  ];
 8
 9  alert( unique(strings) ); // Hare, Krishna, :-O
```
